### **Balanced Array**

Given an array of numbers, find the index of the smallest array element (the pivot), for which the sums of all elements to the left and to the right are equal. The array may not be reordered.

#### Example

arr=[1,2,3,4,6]

- the sum of the first three elements, 1+2+3=6. The value of the last element is 6.
- Using zero based indexing, arr[3]=4 is the pivot between the two subarrays.
- The index of the pivot is 3.

#### Constraints

- 3 ≤ n ≤ 10<sup>5</sup>
- 1  $\leq$  arr[i]  $\leq$  2  $\times$  10<sup>4</sup>, where 0  $\leq$  i  $\leq$  n

It is guaranteed that a solution always exists.

The first line contains an integer n, the size of the array arr. Each of the next n lines contains an integer, arr[i], where  $0 \le i < n$ .

Sample Case 0

Sample Input 0

4

1

2

3

3

Sample Output 0

2

Explanation 0

The sum of the first two elements, 1+2=3. The value of the last element is 3 Using zero based indexing, arr[2]=3 is the pivot between the two subarrays The index of the pivot is 2

Sample Case 1

Sample Input 1

3

1

2

Sample Output 1

1

Explanation 1

The first and last elements are equal to 1

Using zero based indexing, arr[1]=2 is the pivot between the two subarrays. The index of the pivot is 1.

#### For example:

Input	Result
4	2
1	_
2	
3	
3

Check pair with difference k

Given an array A of sorted integers and another non negative integer k, find if there exists 2 indices i and j such that A[i] - A[j] = k, i!=j.

#### Input Format

- First line is number of test cases T. Following T lines contain:
- N, followed by N integers of the array
- 3. The non-negative integer k

Output format

Print 1 if such a pair exists and 0 if it doesn't

Input

## Find the Factor

Determine the factors of a number (i.e., all positive integer values that evenly divide into a number) and then return the p<sup>th</sup> element of the <u>list</u>, sorted ascending. If there is no p<sup>th</sup> element, return 0.

#### Constraints

```
1 \leq n \leq 10^{15}
```

$$1 \le p \le 10^9$$

The first line contains an integer n, the number to factor.

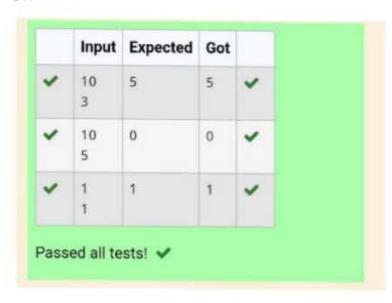

The second line contains an integer p, the 1-based index of the factor to return.

```
Sample Case 0
Sample Input 0
10
Sample Output 0
Explanation 0
Factoring n = 10 results in \{1, 2, 5, 10\}. Return the p = 3^{rd} factor, 5, as the answer.
Sample Case 1
Sample Input 1
10
Sample Output 1
Explanation 1
Factoring n = 10 results in \{1, 2, 5, 10\}. There are only 4 factors and p = 5, therefore
0 is returned as the answer.
Sample Case 2
Sample Input 2
Sample Output 2
```

<= len(factors): return
factors[p - 1]
else:
return 0

# Reading input directly from the standard input (typically for competitive programming) input = sys.stdin.read data = input().split() n = int(data[0])p = int(data[1])

# Calculate and print the p-th factor print(get\_pth\_factor(n, p))

```
def main():
    m = int(input())
    n = int(input())

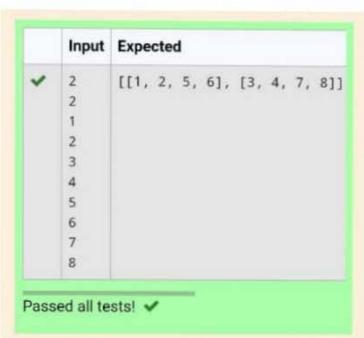

list1 = [[int(input()) for _ in range(n)] for _ in range(m)]

list2 = [[int(input()) for _ in range(n)] for _ in range(m)]

zipped_list = zip_lists(list1, list2)

print(zipped_list)

if __name__ == "__main__":
    main()
```

### **Print Element Location**

Write a program to print all the locations at which a particular element (taken as input) is found in a list and also print the total number of times it occurs in the list. The location starts from 1.

For example, if there are 4 elements in the array: 5 6 5 7 If the element to search is 5 then the output will be: 5 is present at location 1 5 is present at location 3 5 is present 2 times in the array. Sample Test Cases Test Case 1 Input 4 6 5 Output

5 is present at location 1.

5 is present at location 3.

5 is present 2 times in the array.

Test Case 2

```
Input
5
67
80
45
97
100
50
Output
50 is not present in the array.
def find_element_locations(lst, target):
  locations = [] count
= 0 for i in
range(len(lst)):
                    if
lst[i] == target:
     locations.append(i + 1)
count += 1
  return locations, count
def main():
  n = int(input()) lst =
[int(input()) for _ in range(n)]
target = int(input())
  locations, count = find_element_locations(lst, target)
```

```
if count == 0:
    print(f"{target} is not present in the array.")
    else:         for loc in

locations:
    print(f"{target} is present at location {loc}.")

print(f"{target} is present {count} times in the array.")

if __name__ == "__main__":

.

### Strictly increasing

Write a Python program to check if a given list is strictly increasing or not. Moreover, If removing only one element from the list results in a strictly increasing list, we still consider the list true Input:

n: Number of elements

List1: List of values

Output

Print "True" if list is strictly increasing or decreasing else print "False"

Sample Test Case

Input

7

1

2

3

0

4

 $\mathbf{5}$ 

6

Output

True

n= int(input()) arr = [int(input())

for i in range(n)] l = arr.copy() g=0

Distinct Elements in an Array

Program to print all the distinct elements in an array. Distinct elements are nothing but the unique (non-duplicate) elements present in the given array.

Input Format:

First line take an Integer input from stdin which is array length n.

Second line take n Integers which is inputs of array.

Output Format:

Print the Distinct Elements in Array in single line which is space Separated

2
